5.11 Geo Notes

5.11.1 Center of mass

System of points(2D/3D): Mass weighted average of points.
Frame(2D/3D): Get middle point of each segment solve as previously.
Triangle: Average of vertices.
2D Polygon: Compute **signed** area and center of mass of triangle $((0,0), p_i, p_{i+1})$. Then solve as system of points.
Polyhedron surface: Solve each face as a 2D polygon(be aware of (0, 0)) then replace each face with its center of mass and solve as system of points.
Tetrahedron(Triangular pyramid): As triangles, its the average of points.
Polyhedron: Can be done as 2D polygon, but with tetrahedralization intead of triangulation.

5.11.2 Pick's Theorem

Given a polygon without self-intersections and all its vertices on integer coordinates in some 2D grid. Let A be its area, I the number of points with integer coordinates stricly inside the polygon and B the number of points with integer coordinates in the border of the polygon. The following formula holds: $A = I + \frac{B}{2} - 1$.

6.18 Burnside's Lemma

Let $(G, \oplus)$ be a finite group that acts on a set X. It should hold that $e_g * x = x$ and $g_1 * (g_2 * x) = (g_1 \oplus g_2) * x$, $\forall x \in X, g_1, g_2 \in G$. For each $g \in G$ let $X^g = \{x \in X \mid g * x = x\}$. The number of orbits its given by:

$$| X/G | \ = \frac{1}{|G|} \sum_{g \in G} |X^g|$$

6.19 Wilson's Theorem

$(n-1)! = -1 \mod n \iff n$ is prime

6.20 Fibonacci

- $F_{n-1}F_{n+1} - F_n^2 = (-1)^n$
- $F_{n+k} = F_k F_{n+1} + F_{k-1}F_n$
- $GCD(F_n, F_m) = F_{GCD(n,m)}$
- $F_n = \frac{(\frac{1+\sqrt{5}}{2})^n - (\frac{1-\sqrt{5}}{2})^n}{\sqrt{5}}$

6.21 Lucas's Theorem

For non-negative integers m and n and a prime p, the following congruence holds:

$$\binom{m}{n} \equiv \prod_{i=0}^{k} \binom{m_i}{n_i} \pmod{p}$$

where m_i is the i-th digit of m in base p. $\binom{a}{b} = 0$ if $a < b$.

6.22 Kirchhoff's Theorem

Laplacian matrix is $L = D - A$, where D is a diagonal matrix with vertex degrees on the diagonals and A is adjacency matrix.

The number of spanning trees is any cofactor of L. i-th cofactor is determinant of the matrix gotten by removing i-th row and column of L.

6.22.1 Multigraphs

In $D[i][i]$ all loops are excluded. $A[i][j]$ = number of edges from i to j.

6.22.2 Directed multigraphs

$D[i][i]$ = indegree of i minus the number of loops at i. $A[i][j]$ = number of edges from i to j.

The number of oriented spanning trees rooted at a vertex i is the determinant of the matrix gotten by removing the ith row and column of L.

6.23 Matroid

Let X set of objects, $I \subseteq 2^X$ set of independents sets such that:

1. $\emptyset \in I$
2. $A \in I, B \subseteq A \implies B \in I$
3. Exchange axiom, $A \in I, B \in I, |B| > |A| \implies \exists x \in B \setminus A : A \cup \{x\} \in I$
4. $A \subseteq X$ and I and I' are maximal independent subsets of A then $|I| = |I'|$

Then (X, I) is a matroid. The combinatorial optimization problem associated with it is: Given a weight $w(e) \geq 0 \ \forall e \in X$, find an independet subset that has the

largest possible total weight.

6.24 Matroid intersection

55f1a2840ddf17787899e0809856b6bd, 43 lines

```
// Input two matroids (X, I_a) and (X, I_b)
// output set I of maximum size, I \in I_a and I \in I_b
set<> I;
while(1){
    for(e_i : X \ I)
        if(I + e_i \in I_a and I + e_i \in I_b)
            I = I + e_i;
    set<> A, T; queue<> Q;
    for(x : X) label[x] = MARK1;
    for(e_i : X \ I){
        if(I + e_i \in I_a)
            Q.push(e_i), label[e_i] = MARK2;

        else{
            for(x such that I - x + e_i \in I_b)
                A[e_i].push(x);
        }
    }
    if(T.empty()) break;
    bool found = false;
    while(!Q.empty() and !found){
        auto e = Q.front(); Q.pop();
        for(x : A[e]) if(label[x] == MARK1){
            label[x] = e; Q.push(x);
            if(x \in T){
                found = true; put = 1;
                while(label[x] != MARK2){
                    I = put ? (I + x) : (I - x);
                    put = 1 - put;
                }
                I = I + x;
                break;
            }
        }
    }
    if(!found) break;
}
return I;
```

Where path(e) = [e] if label[e] = MARK2, path(label[e]) + [e] otherwise.

6.24.1 Matroid Union

Given k matroids over the same set of objects $(X, I_1), (X, I_2), \ldots, (X, I_k)$ find $A_1 \in I_1, A_2 \in I_2, \ldots, A_k \in I_k$ such that $i \neq j, A_i \cap A_j = \emptyset$ and $|\bigcup_{i=1}^{k} A_i|$ is maximum. Matroid union can be reduced to matroid intersection as follows.

Let $X' = X \times \{1, 2, \ldots, k\}$, ie, k copies of each element of X with different colors. $M1 = (X', Q)$ where $B \in Q \iff \forall\ 1 \leq i \leq k,\ \{x \mid (x, i) \in B\} \in I_i$, ie, for each color, B is independent. $M2 = (X', W)$ where $B \in W \iff i \neq j \implies \neg((x, i) \in B \wedge (x, j) \in B)$, ie, each element is picked by at most one color.

Intersection of $M1$ and $M2$ is the answer for the combinatorial problem of matroid union.

6.25 Notes

When we repeat something and each time we have probability p to succeed then the expected number or tries is $\frac{1}{p}$, till we succeed.

Small to large

Trick in statement If k sets are given you should note that the amount of different set sizes is $O(\sqrt{s})$ where s is total size of those sets. And no more than $\sqrt{s}$ sets have size greater than $\sqrt{s}$. For example, a path to the root in Aho-Corasick through suffix links will have at most $O(\sqrt{s})$ vertices.

gcd on subsegment, we have at most $\log(a_i)$ different values in $\{\gcd(a_j, a_{j+1}, ..., a_i)$ for $j < i\}$.

From static set to expandable. To insert, create a new set with the new element. While there are two sets with same size, merge them. There will be at most $\log(n)$ disjoints sets.

Matrix exponentiation optimization. Save binary power of A_{nxn} and answer q queries $b = A^m x$ in $O((n^3 + qn^2)log(m))$.

Ternary search on integers into binary search, comparing f(mid) and f(mid+1), binary search on derivative

Dynamic offline set For each element we will wind segment of time $[a, b]$ such that element is present in the set during this whole segment. Now we can come up with recursive procedure which handles $[l, r]$ time segment considering that all elements such that $[l, r] \subset [a, b]$ are already included into the set. Now, keeping this invariant we recursively go into $[l, m]$ and $[m + 1, r]$ subsegments. Finally when we come into segment of length 1.

$a > b \implies a \mod b < \frac{a}{2}$

Convex Hull. The expected number of points in the convex hull of a random set of points is $O(log(n))$. The number of points in a convex hull with points coordinates limited by L is $O(L^{2/3})$.

Tree path query. Sometimes the linear query is fast enough. Just do adamant's hld sorting subtrees by their size and remap vertices indexes.

Range query offline can be solved by a sweep, ordering queries by R.

Maximal number of divisors of any n-digit number. 7 4, 12, 32, 64, 128, 240, 448, 768, 1344, 2304, 4032, 6720, 10752, 17280, 26880, 41472, 64512, 103680, 161280, 245760, 368640, 552960, 860160, 1290240, 1966080, 2764800, 4128768, 6193152, 8957952, 13271040, 19660800, 28311552, 41287680, 59719680, 88473600, 127401984, 181665792, 264241152, 382205952, 530841600
